
Unit – 3 : Session – 2 : SLO – 1 | Types of Scheduling Algorithms — Match the Characteristics

Algorithm with its two characteristics

- A. First Come First Serve (FCFS) — non-preemptive and may cause the convoy effect; simple, but not suited for multitasking OS.
- B. Shortest Job First (SJF) — requires precise knowledge of burst time, impractical in real-time systems; gives the lowest average turnaround time if burst time is known.
- C. Round Robin (RR) — fair to all jobs but leads to high context switching under load; supports preemption.
- D. Priority Scheduling — may starve low-priority tasks unless aging is used; supports preemption, useful in real-time systems.
- E. Multilevel Queue Scheduling (MLQ) — fixed queues based on job type, no movement between queues; may increase response time due to overhead and policy decisions.
- F. Multilevel Feedback Queue Scheduling (MLFQ) — adapts priority based on behavior, responsive to process changes; may increase response time due to overhead and policy decisions.
