
Unit – 2 : Session – 5 : SLO – 1 | Client-Server Communication — Fill in the Blanks

Sockets

1. A socket is the endpoint for network communication used by both client and server.
2. The bind function is used to assign an IP address and port to the server socket.
3. The listen function places the server socket into a passive state, ready to accept connections.
4. The accept function allows the server to accept incoming connection requests from clients.
5. The client process initiates the connection to the server.
6. The connect function establishes a connection to the server from the client side.
7. The send function is used to send data over a connected socket.
8. The server is the program that waits for and handles client requests.
9. Communication between client and server typically uses a unique port number to identify the service.
10. Each machine on a network is identified by a unique IP address.
