
Unit – 3 : Session – 9 : SLO – 1 | Multilevel Queue Scheduling — Fill in the Blanks

Multilevel Queue Scheduling

1. Multilevel Queue Scheduling divides the ready queue into multiple separate queues.
2. Foreground queue uses Round Robin scheduling, while background queue uses FCFS.
3. A process is permanently assigned in a given queue; it does not move between queues.
4. In fixed priority scheduling, there is a possibility of starvation for lower-priority processes.
5. MLQ allows setting priorities (or time slices) between processes of different queues.
