

Unit – 5 : Session – 8 : SLO – 2 | Defining and Binding Event Handlers to Widgets

I. Questions & Answers

1. Binding a function to a button — either pass it at creation: `tk.Button(root, text="Go", command=my_func)`; or use the generic binder: `button.bind("<Button-1>", my_handler)` where the handler receives an event object.
2. When a bound function is triggered — the event loop detects the event and calls the handler synchronously on the GUI thread; the handler runs to completion, then control returns to `mainloop()` and the UI updates.
3. Sharing handlers — yes. Multiple widgets can register the same handler; inside it, `event.widget` (or the command's shared state) identifies which widget fired, e.g. one `on_key` handler for several `Entry` fields.
